

# **Chapter 2: Relational Model**

# Chapter 2: Relational Model

- ❏ Structure of Relational Databases
- ❏ Fundamental Relational-Algebra-Operations
- ❏ Additional Relational-Algebra-Operations
- ❏ Extended Relational-Algebra-Operations
- ❏ Null Values
- ❏ Modification of the Database

## Example of a Relation

<i>account_number</i>	<i>branch_name</i>	<i>balance</i>
A-101	Downtown	500
A-102	Perryridge	400
A-201	Brighton	900
A-215	Mianus	700
A-217	Brighton	750
A-222	Redwood	700
A-305	Round Hill	350

# Attribute Types

- ❏ Each attribute of a relation has a name
- ❏ The set of allowed values for each attribute is called the **domain** of the attribute
- ❏ Attribute values are (normally) required to be **atomic**; that is, indivisible
  - ❏ E.g. the value of an attribute can be an account number, but cannot be a set of account numbers
- ❏ Domain is said to be atomic if all its members are atomic
- ❏ The special value *null* is a member of every domain
- ❏ The null value causes complications in the definition of many operations
  - ❏ We shall ignore the effect of null values in our main presentation and consider their effect later

# Relation Schema

☒ Formally, given domains  $D_1, D_2, \dots, D_n$  a **relation**  $r$  is a subset of

$$D_1 \times D_2 \times \dots \times D_n$$

Thus, a relation is a set of  $n$ -tuples  $(a_1, a_2, \dots, a_n)$  where each  $a_i \in D_i$

☒ Schema of a relation consists of

☒ attribute definitions

- ▶ name
- ▶ type/domain

☒ integrity constraints

# Relation Instance

- ❧ The current values (*relation instance*) of a relation are specified by a table
- ❧ An element  $t$  of  $r$  is a *tuple*, represented by a *row* in a table
- ❧ Order of tuples is irrelevant (tuples may be stored in an arbitrary order)

The diagram shows a table representing a relation instance. The table has three columns and four rows. Arrows point from the text 'attributes (or columns)' to the column headers. Another set of arrows points from the text 'tuples (or rows)' to the data rows. The table is labeled 'customer' at the bottom.

<i>customer_name</i>	<i>customer_street</i>	<i>customer_city</i>
<i>Jones</i>	Main	Harrison
<i>Smith</i>	North	Rye
<i>Curry</i>	North	Rye
<i>Lindsay</i>	Park	Pittsfield

*customer*

# Database

- ❧ A database consists of multiple relations
- ❧ Information about an enterprise is broken up into parts, with each relation storing one part of the information
- ❧ E.g.

*account* : information about accounts

*depositor* : which customer owns which account

*customer* : information about customers

# The *customer* Relation

<i>customer_name</i>	<i>customer_street</i>	<i>customer_city</i>
Adams	Spring	Pittsfield
Brooks	Senator	Brooklyn
Curry	North	Rye
Glenn	Sand Hill	Woodside
Green	Walnut	Stamford
Hayes	Main	Harrison
Johnson	Alma	Palo Alto
Jones	Main	Harrison
Lindsay	Park	Pittsfield
Smith	North	Rye
Turner	Putnam	Stamford
Williams	Nassau	Princeton

# The *depositor* Relation

<i>customer_name</i>	<i>account_number</i>
Hayes	A-102
Johnson	A-101
Johnson	A-201
Jones	A-217
Lindsay	A-222
Smith	A-215
Turner	A-305

# Why Split Information Across Relations?

- ❗ Storing all information as a single relation such as  
*bank(account\_number, balance, customer\_name, ..)*  
results in
  - ❗ repetition of information
    - ▶ e.g., if two customers own an account (What gets repeated?)
  - ❗ the need for null values
    - ▶ e.g., to represent a customer without an account
- ❗ Normalization theory (Chapter 7) deals with how to design relational schemas

# Keys

- ❏ Let  $K \subseteq R$
- ❏  $K$  is a **superkey** of  $R$  if values for  $K$  are sufficient to identify a unique tuple of each possible relation  $r(R)$ 
  - ❏ by “possible  $r$ ” we mean a relation  $r$  that could exist in the enterprise we are modeling.
  - ❏ Example:  $\{customer\_name, customer\_street\}$  and  $\{customer\_name\}$   
are both superkeys of *Customer*, if no two customers can possibly have the same name
    - ▶ In real life, an attribute such as *customer\_id* would be used instead of *customer\_name* to uniquely identify customers, but we omit it to keep our examples small, and instead assume customer names are unique.

# Keys (Cont.)

☒  $K$  is a **candidate key** if  $K$  is minimal

Example:  $\{customer\_name\}$  is a candidate key for *Customer*, since it is a superkey and no subset of it is a superkey.

☒ **Primary key:** a candidate key chosen as the principal means of identifying tuples within a relation

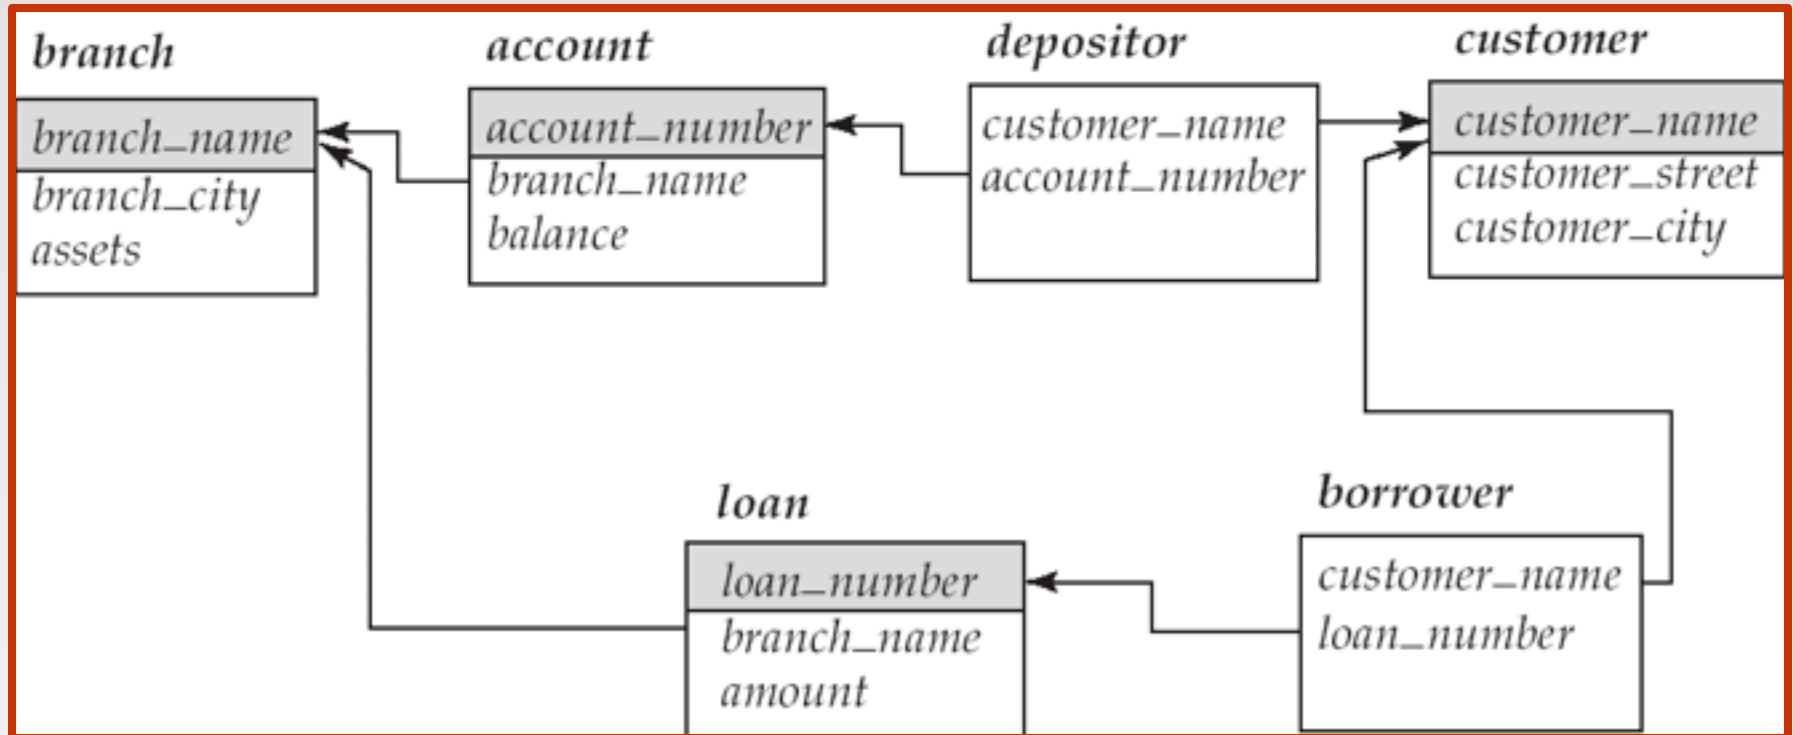

☒ Should choose an attribute whose value never, or very rarely, changes.

☒ E.g. email address is unique, but may change

# Foreign Keys

- ❏ A relation schema may have an attribute that corresponds to the primary key of another relation. The attribute is called a **foreign key**.
- ❏ E.g. *customer\_name* and *account\_number* attributes of *depositor* are foreign keys to *customer* and *account* respectively.
- ❏ Only values occurring in the primary key attribute of the **referenced relation** may occur in the foreign key attribute of the **referencing relation**.

# Schema Diagram

# Query Languages

- ❏ Language in which user requests information from the database.
- ❏ Categories of languages
  - ❏ Procedural
  - ❏ Non-procedural, or declarative
- ❏ “Pure” languages:
  - ❏ Relational algebra
  - ❏ Tuple relational calculus
  - ❏ Domain relational calculus
- ❏ Pure languages form underlying basis of query languages that people use.

# Relational Algebra

- ❏ Procedural language
- ❏ Six basic operators
  - ❏ select:  $\sigma$
  - ❏ project:  $\pi$
  - ❏ union:  $\cup$
  - ❏ set difference:  $-$
  - ❏ Cartesian product:  $\times$
  - ❏ rename:  $\rho$
- ❏ The operators take one or two relations as inputs and produce a new relation as a result.

# Select Operation – Example

 Relation  $r$

$A$	$B$	$C$	$D$
$\alpha$	$\alpha$	1	7
$\alpha$	$\beta$	5	7
$\beta$	$\beta$	12	3
$\beta$	$\beta$	23	10

■  $\sigma_{A=B \wedge D > 5}(r)$

$A$	$B$	$C$	$D$
$\alpha$	$\alpha$	1	7
$\beta$	$\beta$	23	10

# Project Operation – Example

 Relation  $r$ :

$A$	$B$	$C$
$\alpha$	10	1
$\alpha$	20	1
$\beta$	30	1
$\beta$	40	2

$\Pi_{A,C}(r)$

$A$	$C$
$\alpha$	1
$\alpha$	1
$\beta$	1
$\beta$	2

=

$A$	$C$
$\alpha$	1
$\beta$	1
$\beta$	2

# Union Operation – Example

☒ Relations  $r, s$ :

$A$	$B$
$\alpha$	1
$\alpha$	2
$\beta$	1

$r$

$A$	$B$
$\alpha$	2
$\beta$	3

$s$

☒  $r \cup s$ :

$A$	$B$
$\alpha$	1
$\alpha$	2
$\beta$	1
$\beta$	3

# Set Difference Operation – Example

☒ Relations  $r, s$ :

$A$	$B$
$\alpha$	1
$\alpha$	2
$\beta$	1

$r$

$A$	$B$
$\alpha$	2
$\beta$	3

$s$

☒  $r - s$ :

$A$	$B$
$\alpha$	1
$\beta$	1

# Cartesian-Product Operation – Example

 Relations  $r, s$ :

$A$	$B$
$\alpha$	1
$\beta$	2

$r$

$C$	$D$	$E$
$\alpha$	10	$a$
$\beta$	10	$a$
$\beta$	20	$b$
$\gamma$	10	$b$

$s$

  $r \times s$ :

$A$	$B$	$C$	$D$	$E$
$\alpha$	1	$\alpha$	10	$a$
$\alpha$	1	$\beta$	10	$a$
$\alpha$	1	$\beta$	20	$b$
$\alpha$	1	$\gamma$	10	$b$
$\beta$	2	$\alpha$	10	$a$
$\beta$	2	$\beta$	10	$a$
$\beta$	2	$\beta$	20	$b$
$\beta$	2	$\gamma$	10	$b$

# Rename Operation

- ☒ Allows us to name, and therefore to refer to, the results of relational-algebra expressions.
- ☒ Allows us to refer to a relation by more than one name.
- ☒ Example:

$$\rho_x(E)$$

returns the expression  $E$  under the name  $X$

- ☒ If a relational-algebra expression  $E$  has arity  $n$ , then

$$\rho_{x(A_1, A_2, \dots, A_n)}(E)$$

returns the result of expression  $E$  under the name  $X$ , and with the attributes renamed to  $A_1, A_2, \dots, A_n$ .

# Composition of Operations

❏ Can build expressions using multiple operations

❏ Example:  $\sigma_{A=C}(r \times s)$

❏  $r \times s$

<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$\alpha$	1	$\alpha$	10	<i>a</i>
$\alpha$	1	$\beta$	10	<i>a</i>
$\alpha$	1	$\beta$	20	<i>b</i>
$\alpha$	1	$\gamma$	10	<i>b</i>
$\beta$	2	$\alpha$	10	<i>a</i>
$\beta$	2	$\beta$	10	<i>a</i>
$\beta$	2	$\beta$	20	<i>b</i>
$\beta$	2	$\gamma$	10	<i>b</i>

❏  $\sigma_{A=C}(r \times s)$

<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
$\alpha$	1	$\alpha$	10	<i>a</i>
$\beta$	2	$\beta$	10	<i>a</i>
$\beta$	2	$\beta$	20	<i>b</i>

# Banking Example

*branch (branch\_name, branch\_city, assets)*

*customer (customer\_name, customer\_street, customer\_city)*

*account (account\_number, branch\_name, balance)*

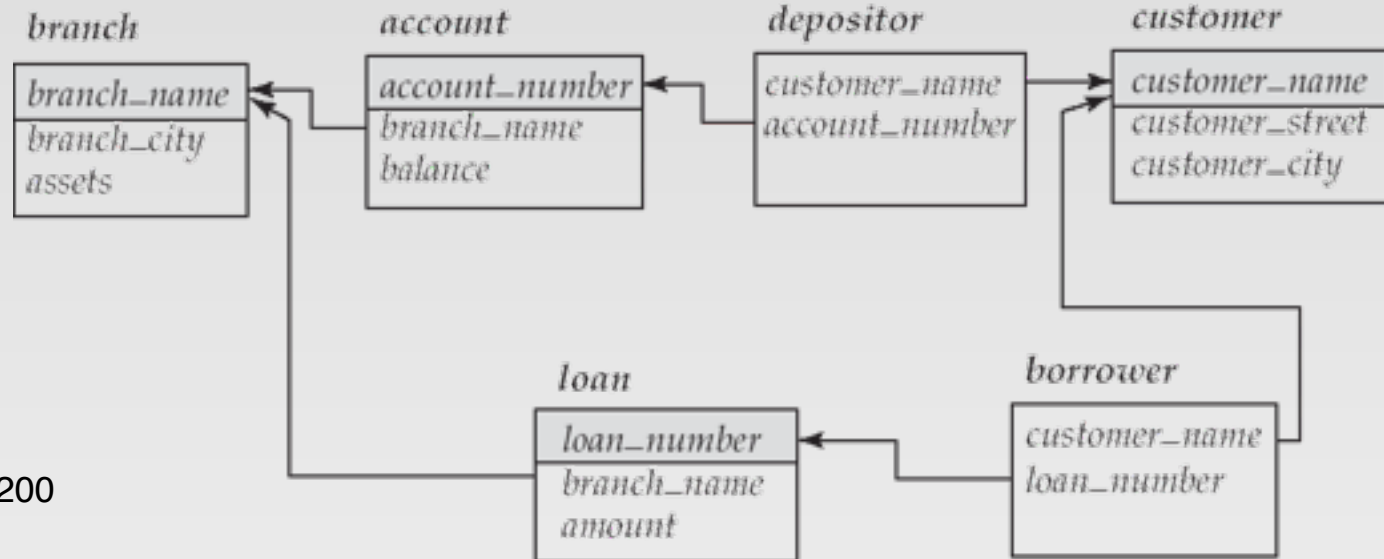

*loan (loan\_number, branch\_name, amount)*

*depositor (customer\_name, account\_number)*

*borrower (customer\_name, loan\_number)*

# Example Queries

Find all loans of over \$1200

$$\sigma_{amount > 1200} (loan)$$

Find the loan number for each loan of an amount greater than \$1200

$$\Pi_{loan\_number} (\sigma_{amount > 1200} (loan))$$

Find the names of all customers who have a loan, an account, or both, from the bank

$$\Pi_{customer\_name} (borrower) \cup \Pi_{customer\_name} (depositor)$$

Prepared By: Dr. Shalini Bhaskar Bajaj

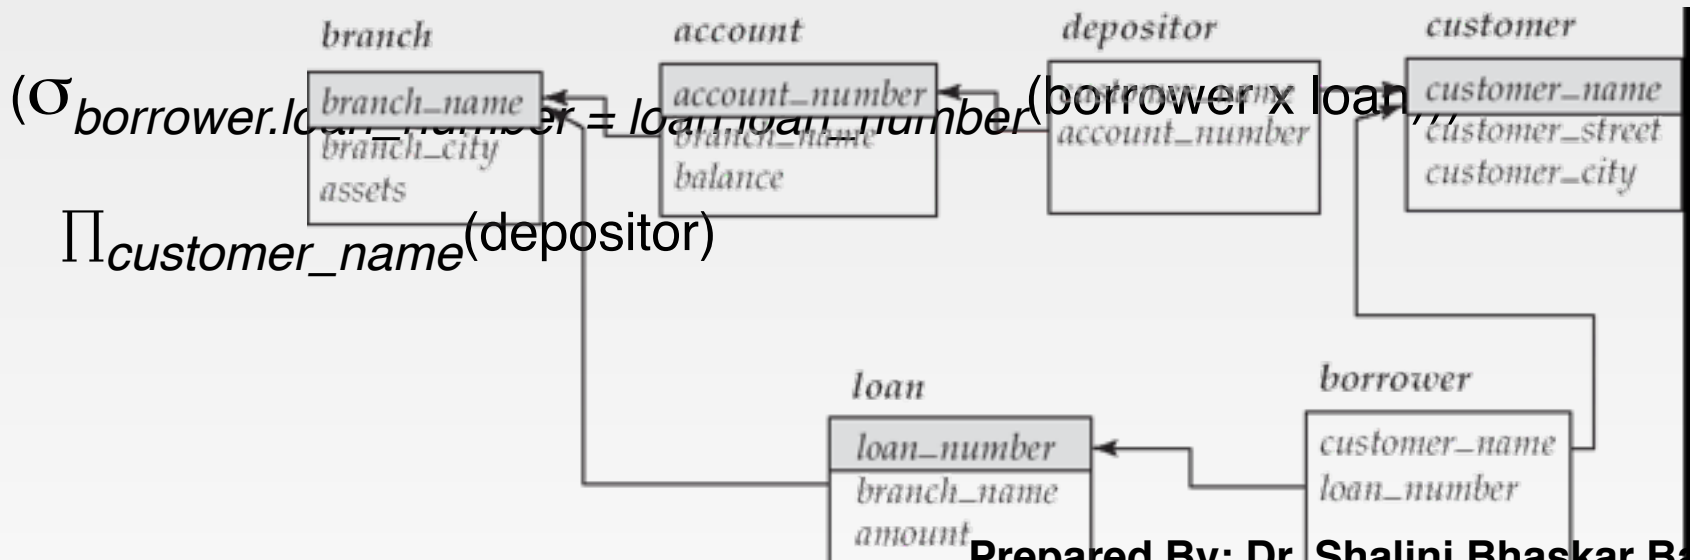

# Example Queries

- Find the names of all customers who have a loan at the Perryridge branch.

$$\Pi_{customer\_name} (\sigma_{branch\_name="Perryridge"} ($$

$$(\sigma_{borrower.loan\_number = loan.loan\_number} (borrower \times loan)))$$

- Find the names of all customers who have a loan at the Perryridge branch but do not have an account at any branch of the bank.

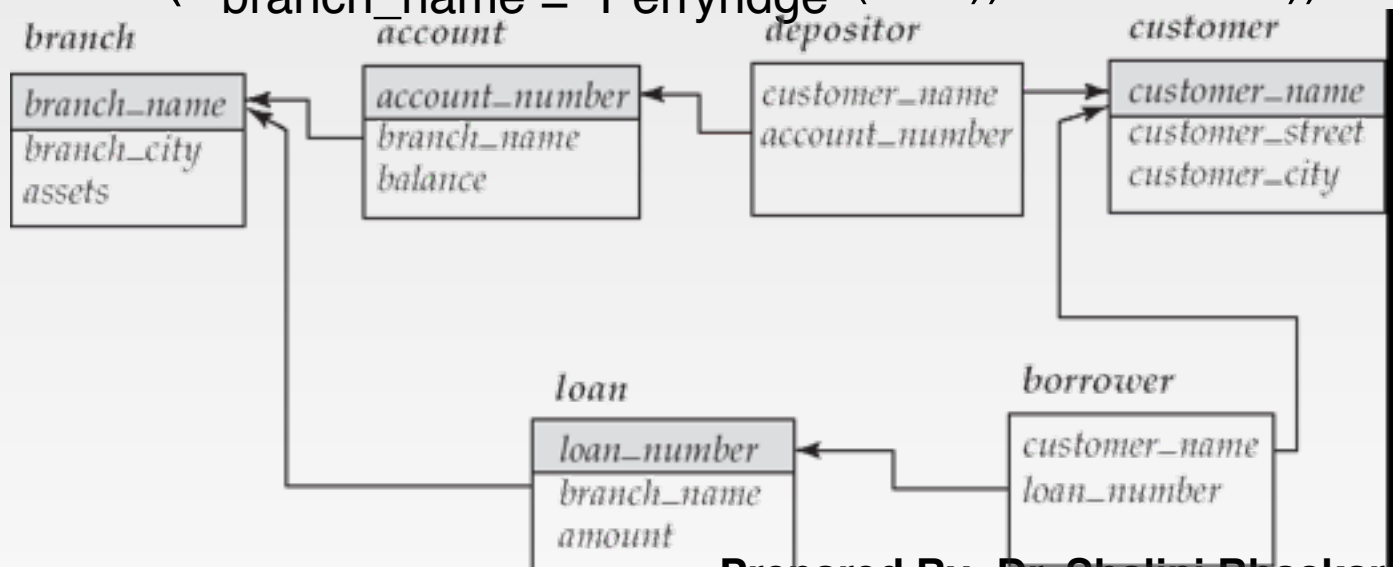

$$\Pi_{customer\_name} (\sigma_{branch\_name = "Perryridge"} ($$

# Example Queries

Find the names of all customers who have a loan at the Perryridge branch.

$\Pi_{\text{customer\_name}} (\sigma_{\text{branch\_name} = \text{"Perryridge"}} ( \sigma_{\text{borrower.loan\_number} = \text{loan.loan\_number}} (\text{borrower} \times \text{loan})))$

$\Pi_{\text{customer\_name}} (\sigma_{\text{loan.loan\_number} = \text{borrower.loan\_number}} ( \sigma_{\text{branch\_name} = \text{"Perryridge"}} (\text{loan})) \times \text{borrower}))$

# Additional Operations

- ❏ Additional Operations
  - ❏ Set intersection
  - ❏ Natural join
  - ❏ Aggregation
  - ❏ Outer Join
  - ❏ Division
- ❏ All above, other than aggregation, can be expressed using basic operations we have seen earlier

# Set-Intersection Operation – Example

Relation  $r, s$ :

A	B
$\alpha$	1
$\alpha$	2
$\beta$	1

$r$

A	B
$\alpha$	2
$\beta$	3

$s$

$r \cap s$

A	B
$\alpha$	2

# Natural Join Operation – Example

Relations  $r$ ,  $s$ :

$A$	$B$	$C$	$D$
$\alpha$	1	$\alpha$	a
$\beta$	2	$\gamma$	a
$\gamma$	4	$\beta$	b
$\alpha$	1	$\gamma$	a
$\delta$	2	$\beta$	b

$r$

$B$	$D$	$E$
1	a	$\alpha$
3	a	$\beta$
1	a	$\gamma$
2	b	$\delta$
3	b	$\epsilon$

$s$

$r \bowtie s$

$A$	$B$	$C$	$D$	$E$
$\alpha$	1	$\alpha$	a	$\alpha$
$\alpha$	1	$\alpha$	a	$\gamma$
$\alpha$	1	$\gamma$	a	$\alpha$
$\alpha$	1	$\gamma$	a	$\gamma$
$\delta$	2	$\beta$	b	$\delta$

# Natural-Join Operation

☒ Notation:  $r \bowtie s$

☒ Let  $r$  and  $s$  be relations on schemas  $R$  and  $S$  respectively.  
Then,  $r \bowtie s$  is a relation on schema  $R \cup S$  obtained as follows:

☒ Consider each pair of tuples  $t_r$  from  $r$  and  $t_s$  from  $s$ .

☒ If  $t_r$  and  $t_s$  have the same value on each of the attributes in  $R \cap S$ , add a tuple  $t$  to the result, where

▶  $t$  has the same value as  $t_r$  on  $r$

▶  $t$  has the same value as  $t_s$  on  $s$

☒ Example:

$R = (A, B, C, D)$

$S = (E, B, D)$

☒ Result schema =  $(A, B, C, D, E)$

☒  $r \bowtie s$  is defined as:

$$\Pi_{r.A, r.B, r.C, r.D, s.E} (\sigma_{r.B = s.B \wedge r.D = s.D} (r \times s))$$

# Bank Example Queries

Find the largest account balance

Strategy:

- Find those balances that are *not* the largest
  - Rename *account* relation as *d* so that we can compare each account balance with all others
- Use set difference to find those account balances that were *not* found in the earlier step.

The query is:

$$\Pi_{balance}(account) - \Pi_{account.balance}$$

$$(\sigma_{account.balance < d.balance} (account \times \rho_d (account)))$$

*account*

<i>account_number</i>
<i>branch_name</i>
<i>balance</i>

# Aggregate Functions and Operations

☒ **Aggregation function** takes a collection of values and returns a single value as a result.

**avg**: average value

**min**: minimum value

**max**: maximum value

**sum**: sum of values

**count**: number of values

☒ **Aggregate operation** in relational algebra

$$G_1, G_2, \dots, G_n \ \vartheta_{F_1(A_1), F_2(A_2), \dots, F_n(A_n)}(E)$$

$E$  is any relational-algebra expression

☒  $G_1, G_2, \dots, G_n$  is a list of attributes on which to group (can be empty)

☒ Each  $F_i$  is an aggregate function

☒ Each  $A_i$  is an attribute name

# Aggregate Operation – Example

Relation  $r$ :

$A$	$B$	$C$
$\alpha$	$\alpha$	7
$\alpha$	$\beta$	7
$\beta$	$\beta$	3
$\beta$	$\beta$	10

$g_{\text{sum}(c)}(r)$

<b>sum(<math>c</math>)</b>
27

# Aggregate Operation – Example

 Relation *account* grouped by *branch-name*:

<i>branch_name</i>	<i>account_number</i>	<i>balance</i>
Perryridge	A-102	400
Perryridge	A-201	900
Brighton	A-217	750
Brighton	A-215	750
Redwood	A-222	700

*branch\_name*  $\mathcal{G}$  **sum**(*balance*) (*account*)

<i>branch_name</i>	<b>sum</b> ( <i>balance</i> )
Perryridge	1300
Brighton	1500
Redwood	700

# Aggregate Functions (Cont.)

- ❏ Result of aggregation does not have a name
  - ❏ Can use rename operation to give it a name
  - ❏ For convenience, we permit renaming as part of aggregate operation

*branch\_name* **g** **sum**(*balance*) **as** *sum\_balance* (*account*)

# Outer Join

- ❏ An extension of the join operation that avoids loss of information.
- ❏ Computes the join and then adds tuples from one relation that does not match tuples in the other relation to the result of the join.
- ❏ Uses *null* values:
  - ❏ *null* signifies that the value is unknown or does not exist
    - ▶ We shall study precise meaning of comparisons with nulls later

# Outer Join – Example

 Relation *loan*

<i>loan_number</i>	<i>branch_name</i>	<i>amount</i>
L-170	Downtown	3000
L-230	Redwood	4000
L-260	Perryridge	1700

 Relation *borrower*

<i>customer_name</i>	<i>loan_number</i>
Jones	L-170
Smith	L-230
Hayes	L-155

# Outer Join – Example

 Join

*loan* ⋈ *borrower*

<i>loan_number</i>	<i>branch_name</i>	<i>amount</i>	<i>customer_name</i>
L-170	Downtown	3000	Jones
L-230	Redwood	4000	Smith

 Left Outer Join

*loan* ⋈<sub>L</sub> *borrower*

<i>loan_number</i>	<i>branch_name</i>	<i>amount</i>	<i>customer_name</i>
L-170	Downtown	3000	Jones
L-230	Redwood	4000	Smith
L-260	Perryridge	1700	<i>null</i>

# Outer Join – Example

## Right Outer Join

*loan*  *borrower*

<i>loan_number</i>	<i>branch_name</i>	<i>amount</i>	<i>customer_name</i>
L-170	Downtown	3000	Jones
L-230	Redwood	4000	Smith
L-155	<i>null</i>	<i>null</i>	Hayes

## Full Outer Join

*loan*  *borrower*

<i>loan_number</i>	<i>branch_name</i>	<i>amount</i>	<i>customer_name</i>
L-170	Downtown	3000	Jones
L-230	Redwood	4000	Smith
L-260	Perryridge	1700	<i>null</i>
L-155	<i>null</i>	<i>null</i>	Hayes

# Null Values

- ❖ It is possible for tuples to have a null value, denoted by *null*, for some of their attributes
- ❖ *null* signifies an unknown value or that a value does not exist.
- ❖ Aggregate functions simply ignore null values (as in SQL)
- ❖ For duplicate elimination and grouping, null is treated like any other value, and two nulls are assumed to be the same (as in SQL)

# Division Operation

- ❏ Notation:  $r \div s$
- ❏ Suited to queries that include the phrase “for all”.
- ❏ Let  $r$  and  $s$  be relations on schemas  $R$  and  $S$  respectively where

$$\text{❏ } R = (A_1, \dots, A_m, B_1, \dots, B_n)$$

$$\text{❏ } S = (B_1, \dots, B_n)$$

The result of  $r \div s$  is a relation on schema

$$R - S = (A_1, \dots, A_m)$$

$$r \div s = \{ t \mid t \in \prod_{R-S}(r) \wedge \forall u \in s (tu \in r) \}$$

Where  $tu$  means the concatenation of tuples  $t$  and  $u$  to produce a single tuple

# Division Operation – Example

Relations  $r, s$ :

$A$	$B$
$\alpha$	1
$\alpha$	2
$\alpha$	3
$\beta$	1
$\gamma$	1
$\delta$	1
$\delta$	3
$\delta$	4
$\in$	6
$\in$	1
$\beta$	2

$r$

$B$
1
2

$s$

$r \div s$ :

$A$
$\alpha$
$\beta$

# Another Division Example

Relations  $r, s$ :

$A$	$B$	$C$	$D$	$E$
$\alpha$	$a$	$\alpha$	$a$	$1$
$\alpha$	$a$	$\gamma$	$a$	$1$
$\alpha$	$a$	$\gamma$	$b$	$1$
$\beta$	$a$	$\gamma$	$a$	$1$
$\beta$	$a$	$\gamma$	$b$	$3$
$\gamma$	$a$	$\gamma$	$a$	$1$
$\gamma$	$a$	$\gamma$	$a$	$1$
$\gamma$	$a$	$\beta$	$b$	$1$
$\gamma$	$a$	$b$	$b$	$1$

$r$

$D$	$E$
$a$	$1$
$b$	$1$

$s$

$r \div s$ :

$A$	$B$	$C$
$\alpha$	$a$	$\gamma$
$\gamma$	$a$	$\gamma$

# Division Operation (Cont.)

## Property

Let  $q = r \div s$

Then  $q$  is the largest relation satisfying  $q \times s \subseteq r$

## Definition in terms of the basic algebra operation

Let  $r(R)$  and  $s(S)$  be relations, and let  $S \subseteq R$

$$r \div s = \Pi_{R-S}(r) - \Pi_{R-S}((\Pi_{R-S}(r) \times s) - \Pi_{R-S,S}(r))$$

To see why

$\Pi_{R-S,S}(r)$  simply reorders attributes of  $r$

$\Pi_{R-S}(\Pi_{R-S}(r) \times s) - \Pi_{R-S,S}(r)$  gives those tuples  $t$  in

$\Pi_{R-S}(r)$  such that for some tuple  $u \in s$ ,  $tu \notin r$ .

# Bank Example Queries

-  Find the names of all customers who have a loan and an account at bank.

$$\Pi_{customer\_name} (borrower) \cap \Pi_{customer\_name} (depositor)$$

-  Find the name of all customers who have a loan at the bank and the loan amount

$$\Pi_{customer\_name, loan\_number, amount} (borrower \bowtie loan)$$

# Bank Example Queries

- Find all customers who have an account from at least the “Downtown” and the Uptown” branches.

## Query 1

$$\Pi_{customer\_name} (\sigma_{branch\_name = \text{“Downtown”}} (depositor \bowtie account)) \cap \\ \Pi_{customer\_name} (\sigma_{branch\_name = \text{“Uptown”}} (depositor \bowtie account))$$

## Query 2

$$\Pi_{customer\_name, branch\_name} (depositor \bowtie account) \\ \div \rho_{temp(branch\_name)} (\{(\text{“Downtown”}), (\text{“Uptown”})\})$$

Note that Query 2 uses a constant relation.

# Bank Example Queries

-  Find all customers who have an account at all branches located in Brooklyn city.

$$\Pi_{customer\_name, branch\_name} ( depositor \bowtie account ) \\ \div \Pi_{branch\_name} ( \sigma_{branch\_city = \text{"Brooklyn"}} ( branch ) )$$

# **End of Chapter 2**

# Formal Definition

- ❏ A basic expression in the relational algebra consists of either one of the following:
  - ❏ A relation in the database
  - ❏ A constant relation
- ❏ Let  $E_1$  and  $E_2$  be relational-algebra expressions; the following are all relational-algebra expressions:
  - ❏  $E_1 \cup E_2$
  - ❏  $E_1 - E_2$
  - ❏  $E_1 \times E_2$
  - ❏  $\sigma_P(E_1)$ ,  $P$  is a predicate on attributes in  $E_1$
  - ❏  $\Pi_S(E_1)$ ,  $S$  is a list consisting of some of the attributes in  $E_1$
  - ❏  $\rho_x(E_1)$ ,  $x$  is the new name for the result of  $E_1$

# Select Operation

- ❧ Notation:  $\sigma_p(r)$
- ❧  $p$  is called the **selection predicate**
- ❧ Defined as:

$$\sigma_p(r) = \{t \mid t \in r \text{ and } p(t)\}$$

Where  $p$  is a formula in propositional calculus consisting of **terms** connected by :  $\wedge$  (**and**),  $\vee$  (**or**),  $\neg$  (**not**)

Each **term** is one of:

$\langle \text{attribute} \rangle \quad op \quad \langle \text{attribute} \rangle \text{ or } \langle \text{constant} \rangle$

where  $op$  is one of:  $=, \neq, >, \geq, <, \leq$

- ❧ Example of selection:

$$\sigma_{\text{branch\_name}=\text{"Perryridge"}}(\text{account})$$

# Project Operation

☒ Notation:

$$\Pi_{A_1, A_2, \dots, A_k}(r)$$

where  $A_1, A_2$  are attribute names and  $r$  is a relation name.

- ☒ The result is defined as the relation of  $k$  columns obtained by erasing the columns that are not listed
- ☒ Duplicate rows removed from result, since relations are sets
- ☒ Example: To eliminate the *branch\_name* attribute of *account*

$$\Pi_{\text{account\_number, balance}}(\text{account})$$

# Union Operation

☒ Notation:  $r \cup s$

☒ Defined as:

$$r \cup s = \{t \mid t \in r \text{ or } t \in s\}$$

☒ For  $r \cup s$  to be valid.

1.  $r, s$  must have the *same* **arity** (same number of attributes)
2. The attribute domains must be **compatible** (example: 2<sup>nd</sup> column of  $r$  deals with the same type of values as does the 2<sup>nd</sup> column of  $s$ )

☒ Example: to find all customers with either an account or a loan

$$\Pi_{customer\_name}(depositor) \cup \Pi_{customer\_name}(borrower)$$

# Set Difference Operation

❏ Notation  $r - s$

❏ Defined as:

$$r - s = \{t \mid t \in r \text{ and } t \notin s\}$$

❏ Set differences must be taken between **compatible** relations.

❏  $r$  and  $s$  must have the **same** arity

❏ attribute domains of  $r$  and  $s$  must be compatible

# Cartesian-Product Operation

❏ Notation  $r \times s$

❏ Defined as:

$$r \times s = \{t \mid t \in r \text{ and } q \in s\}$$

❏ Assume that attributes of  $r(R)$  and  $s(S)$  are disjoint. (That is,  $R \cap S = \emptyset$ ).

❏ If attributes of  $r$  and  $s$  are not disjoint, then renaming must be used.

# Set-Intersection Operation

- ❏ Notation:  $r \cap s$
- ❏ Defined as:
- ❏  $r \cap s = \{ t \mid t \in r \text{ and } t \in s \}$
- ❏ Assume:
  - ❏  $r, s$  have the *same arity*
  - ❏ attributes of  $r$  and  $s$  are compatible
- ❏ Note:  $r \cap s = r - (r - s)$

# Assignment Operation

- ❏ The assignment operation ( $\leftarrow$ ) provides a convenient way to express complex queries.
- ❏ Write query as a sequential program consisting of
  - ▶ a series of assignments
  - ▶ followed by an expression whose value is displayed as a result of the query.
- ❏ Assignment must always be made to a temporary relation variable.

❏ Example: Write  $r \div s$  as

$$temp1 \leftarrow \prod_{R-S}(r)$$

$$temp2 \leftarrow \prod_{R-S}((temp1 \times s) - \prod_{R-S,S}(r))$$

$$result = temp1 - temp2$$

- ❏ The result to the right of the  $\leftarrow$  is assigned to the relation variable on the left of the  $\leftarrow$ .
- ❏ May use variable in subsequent expressions.

# Extended Relational-Algebra-Operations

-  Generalized Projection
-  Aggregate Functions
-  Outer Join

# Generalized Projection

- Extends the projection operation by allowing arithmetic functions to be used in the projection list.

$$\Pi_{F_1, F_2, \dots, F_n}(E)$$

- $E$  is any relational-algebra expression
- Each of  $F_1, F_2, \dots, F_n$  are arithmetic expressions involving constants and attributes in the schema of  $E$ .
- Given relation *credit\_info(customer\_name, limit, credit\_balance)*, find how much more each person can spend:

$$\Pi_{customer\_name, limit - credit\_balance}(credit\_info)$$

# Modification of the Database

- ❧ The content of the database may be modified using the following operations:
  - ❧ Deletion
  - ❧ Insertion
  - ❧ Updating
- ❧ All these operations are expressed using the assignment operator.

# Deletion

- ❗ A delete request is expressed similarly to a query, except instead of displaying tuples to the user, the selected tuples are removed from the database.
- ❗ Can delete only whole tuples; cannot delete values on only particular attributes
- ❗ A deletion is expressed in relational algebra by:

$$r \leftarrow r - E$$

where  $r$  is a relation and  $E$  is a relational algebra query.

# Deletion Examples

- ❗ Delete all account records in the Perryridge branch.

$$account \leftarrow account - \sigma_{branch\_name = "Perryridge"}(account)$$

- ❗ Delete all loan records with amount in the range of 0 to 50

$$loan \leftarrow loan - \sigma_{amount \geq 0 \text{ and } amount \leq 50}(loan)$$

- ❗ Delete all accounts at branches located in Needham.

$$r_1 \leftarrow \sigma_{branch\_city = "Needham"}(account \bowtie branch)$$
$$r_2 \leftarrow \Pi_{account\_number, branch\_name, balance}(r_1)$$
$$r_3 \leftarrow \Pi_{customer\_name, account\_number}(r_2 \bowtie depositor)$$
$$account \leftarrow account - r_2$$
$$depositor \leftarrow depositor - r_3$$

# Insertion

- ❏ To insert data into a relation, we either:
  - ❏ specify a tuple to be inserted
  - ❏ write a query whose result is a set of tuples to be inserted
- ❏ in relational algebra, an insertion is expressed by:

$$r \leftarrow r \cup E$$

where  $r$  is a relation and  $E$  is a relational algebra expression.

- ❏ The insertion of a single tuple is expressed by letting  $E$  be a constant relation containing one tuple.

# Insertion Examples

-  Insert information in the database specifying that Smith has \$1200 in account A-973 at the Perryridge branch.

$$\begin{aligned} \text{account} &\leftarrow \text{account} \cup \{(\text{"A-973"}, \text{"Perryridge"}, 1200)\} \\ \text{depositor} &\leftarrow \text{depositor} \cup \{(\text{"Smith"}, \text{"A-973"})\} \end{aligned}$$

-  Provide as a gift for all loan customers in the Perryridge branch, a \$200 savings account. Let the loan number serve as the account number for the new savings account.

$$\begin{aligned} r_1 &\leftarrow (\sigma_{\text{branch\_name} = \text{"Perryridge"}}(\text{borrower} \bowtie \text{loan})) \\ \text{account} &\leftarrow \text{account} \cup \Pi_{\text{loan\_number}, \text{branch\_name}, 200}(r_1) \\ \text{depositor} &\leftarrow \text{depositor} \cup \Pi_{\text{customer\_name}, \text{loan\_number}}(r_1) \end{aligned}$$

# Updating

- ❖ A mechanism to change a value in a tuple without changing *all* values in the tuple
- ❖ Use the generalized projection operator to do this task

$$r \leftarrow \prod_{F_1, F_2, \dots, F_l} (r)$$

- ❖ Each  $F_i$  is either
  - ❖ the  $i^{\text{th}}$  attribute of  $r$ , if the  $i^{\text{th}}$  attribute is not updated, or,
  - ❖ if the attribute is to be updated  $F_i$  is an expression, involving only constants and the attributes of  $r$ , which gives the new value for the attribute

# Update Examples

- ☒ Make interest payments by increasing all balances by 5 percent.

$account \leftarrow \Pi_{account\_number, branch\_name, balance * 1.05} (account)$

- ☒ Pay all accounts with balances over \$10,000 6 percent interest and pay all others 5 percent

$account \leftarrow \Pi_{account\_number, branch\_name, balance * 1.06} (\sigma_{BAL > 10000} (account))$   
 $\cup \Pi_{account\_number, branch\_name, balance * 1.05} (\sigma_{BAL \leq 10000} (account))$
